## United States Happiness Index

Considering that every collection of data tends to vary in the range in time the data was collected, the focus of this project spans the past 25 years, starting from 1975 and ending around the year 2020. The main topic of interest covers the waving happiness level of the United States population and a comparison of various factors that may have influenced the general joy consensus.

The measure between gender may differ greatly, so while there should be charts concerning data that measures the population as a collective entity, there should also be separate analysis of certain factors based on gender. There is a comparison of life expectancy placed alongside measured happiness statistics, as the further one ages, the more problems may arise such as dementia or other health factors. The education and literacy rates of the population may also have a direct impact on how pleasant life is for an individual since these two measurements may directly correlate with employment numbers as well as average wage.

The current state of the country may also have a direct impact. A timeline of major events should be provided in order to show how world and or domestic affairs could affect the other factors measured. These events could influence the GDP measure of the country, as well as the public trust in the government.
